Fluorescent Nanodiamonds Nanodiamond particles, also known as nanodiamonds, are exceptional fluorescent nanoparticles which can be used in many ways in Nanotechnology. From nanocrystals, through to fluorescent nanodiamonds, the applications and potential of fluorescent nanoparticles is rapidly increasing as researchers discover new uses for them. In this article, I will briefly look at the different ways you can use fluorescent nanoparticles, and the strengths and weaknesses of each method. Understanding fluorescence Understanding the different kinds of fluorescent nanoparticles can be tricky to navigate and understand. The best way to understand them is to first have some experience with them so it is easier to differentiate between the different types. Different kinds of fluorescence In this section we will cover how fluorescent nanoparticles work and the different kinds of nanoparticles available. In doing so we will cover the following questions: • What is fluorescence? • What is fluorescence spectroscopy? • How do fluorescent nanoparticles work? What is fluorescence? Simply put, fluorescence is the emission of visible light. This emission of light is often due to the presence of an excited electron in an otherwise non-excited material. This phenomenon requires two substances, an excited electron (also called the quencher), and a material that can be made to fluoresce (also called the fluorophore). Every material has an inherent ability to fluoresce, but the ability can be altered by the presence of another electron nearby. The excited electron in a fluorescent nanoparticle can be made to fluoresce the material by the addition of, often, an organic molecule, or by the addition of a metal. The organic molecule is called a fluorophore. The metal is called a quencher. The presence of the metal ion quenches the fluorescence. In other words, if the metal is present in a fluorescent material, it will absorb energy normally given off by the material, thus removing it from its excited state. This is the main reason why all fluorescent materials are paired with an appropriate metal ion as a quencher. This is because many of the metals have either a low energy level or a certain energetic wavelength that reduces the energy of the excited electron. The addition of the fluorophore then allows the material to fluoresce again, emitting the fluorescent light. Fluorophores are often organic molecules, which absorb light
